Abstract

To accelerate the execution of an application, repetitive logic and arithmetic computation tasks may be mapped to reconfigurable hardware, since dedicated hardware can deliver much higher speeds than those of a general-purpose processor. However, this is only feasible if the run-time reconfiguration of new tasks is fast enough, so as not to delay application execution. Currently, this is opposed by architectural constraints intrinsic to current Field-Programmable Logic Array (FPGA) architectures. Despite all new features exhibited by current FPGAs, architecturally they are still largely based on general-purpose architectures that are inadequate for the demands of reconfigurable computing. Large configuration file sizes and poor hardware and software support for partial and dynamic reconfiguration limits the acceleration that reconfigurable computing may bring to applications.

The objective of this work is the identification of the architectural limitations exhibited by current FPGAs that prevent reconfigurable computing systems to achieve a high efficiency and performance and the proposal of alternatives to its resolution.

1. The Problem

In recent years, reconfigurable computing attracted a lot of attention due to its promise to deliver the high performance provided by reconfigurable hardware along with the flexibility of general purpose processors. This perception is based upon a number of technological advancements that led to current generation of mega-gate chips and to a diverse range of features. One particular feature is the ability to partially reconfigure the FPGA, enabling the configuration of application-specific hardware at run-time. Portions of an application, usually referred to as tasks, are mapped to the reconfigurable hardware, while the general-purpose processor handles other tasks. The aim is to

accelerate application execution, by transferring the execution of computing-intensive highly-repetitive tasks to application-specific hardware implemented in reconfigurable devices. This means that the reconfigurable device attached to the system is reused for the implementation of different logic and arithmetic tasks, being re-configured frequently during run-time.

However, despite all the new features, current FPGAs are still largely based on general-purpose architectures that are inadequate for the demands of reconfigurable computing. Some architectural limitations hamper firstly the placement of new tasks, and secondly their fast relocation into the FPGA, preventing the efficient management of the logic space available, and, as a result, leading to a delay on task execution, compromising the benefits of the reconfigurable computing concept. Large configuration file sizes and poor hardware and software support makes partial and dynamic reconfiguration difficult and inefficient. Furthermore, originally designed for rapid prototyping, FPGAs do not emphasize rapid reconfiguration, which limits the acceleration reconfigurable computing may add to applications.

Depending on the application flow, configuration loadings may be carried out along with other computational tasks performed by the host processor, thereby reducing reconfiguration overhead. But this is only true if the application flow, and therefore the sequence of tasks to be configured, is known in advance. Furthermore, execution delays will only be avoided if enough reconfigurable resources are available when required to implement incoming tasks, meaning that tasks have to be pre-synthesised. Otherwise, the time it takes to synthesise them at runtime may lead to an application halt. Hence, there is no flexibility on the placement of tasks and extra resources may be needed just to try to ensure that all tasks will be available when required, decreasing system efficiency.
