

CARBON AND SILICON

organic and virtual thinking materials

Twenty-three percent of you is carbon. The most underpin organic chemistry, the fabric of life, from proteins in our cells to once living small plants and animals.

Coming in a dazzling array of molecules, carbon is electropositive nor negative. A nonmetal, it combines with many other elements and also extensively with itself in long chains and rings (see page 11). Multiple bonds are common between atoms to give double and triple bonds.

Carbon arranges at several different allotropic forms. In diamond crystals every atom bonds to four others in a tetrahedral arrangement (right) whereas in graphite, a soft crystalline solid (left), charcoal and pencils, flat planes of carbon rings slide past each other (top left). Each atom here joins to three others by π -bonds enabling it to conduct electricity.

Other carbon allotropes include a series of spherical molecules, the Buckminsterfullerenes, and interlocking networks that self-assemble in the right conditions.

Directly beneath carbon in the periodic table is silicon, a metalloid semiconductor. Carbon life is mirrored by silicon logic in the buzzing mazes of electronic microchips. They consist of purified silicon crystals, doped with elements like gallium or arsenic to alter their conducting properties.

Stable silicon compounds cover over a quarter of the known rocks and sand; and clays, silicates with unusual life-like chemistries, perhaps even led to biological evolution.
